

# NEUROLOGICAL LOCALISATION

## SYMPTOM-BASED HISTORY & EXAMINATION

---

**Bedside teaching reference** · History → Examination → Anatomical structure

Curated by Anupam Singh MD, Professor, Department of Medicine, Santosh Medical College

**Core rule:** Describe the symptom precisely, identify the second neurological abnormality, then ask: “*What single anatomical lesion can explain all the findings?*” The tables below are designed as a pre-case framework before working through localisation cases.

## Symptom Index — 14 Localisation Domains

1. Diplopia

2. Aphasia

3. Weakness — proximal vs distal

**4. Gait abnormality**

**5. Numbness / sensory symptoms**

**6. Vertigo / dizziness**

**7. Dysarthria, dysphagia & dysphonia**

**8. Visual loss / field disturbance**

**9. Bladder, bowel & sexual dysfunction**

**10. Tremor & involuntary movements**

**11. Headache**

**12. Syncope / transient loss of consciousness**

**13. Seizure**

**14. Memory loss**

01

# Diplopia

Localise: ocular surface → extraocular muscle/NMJ → CN III/IV/VI → MLF/PPRF → cavernous sinus/orbital apex → brainstem

**How to think:** Start with monocular vs binocular. Then define horizontal/vertical separation, gaze dependence, ptosis, pupil change, facial numbness, visual loss and long-tract signs.

| Positive history findings / what to ask        | Positive examination findings / what to elicit                        | Structure / localisation                                                          |
|------------------------------------------------|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Diplopia persists when one eye is covered      | Check each eye separately; inspect ocular surface/refraction          | <b>Monocular diplopia — eye/refractive media</b>                                  |
| Diplopia disappears when either eye is covered | Confirm ocular misalignment; test eye movements in all directions     | <b>Binocular diplopia — EOM/CN III, IV, VI/ NMJ/brainstem</b>                     |
| Horizontal separation of images                | Test abduction and adduction of each eye                              | <b>CN VI/lateral rectus, medial rectus/CN III, MLF or horizontal gaze pathway</b> |
| Vertical or oblique separation                 | Look for hypertropia; test elevation/ depression and head-tilt effect | <b>CN IV, CN III or central skew deviation</b>                                    |
| Worse looking toward one particular side       | H-pattern; identify the weak muscle in its field of action            | <b>Individual EOM / corresponding ocular motor nerve</b>                          |

| Positive history findings / what to ask                       | Positive examination findings / what to elicit                         | Structure / localisation                                              |
|---------------------------------------------------------------|------------------------------------------------------------------------|-----------------------------------------------------------------------|
| Worse on reading or walking downstairs                        | Test depression of the adducted eye;<br>Bielschowsky head-tilt pattern | <b>CN IV / superior oblique</b>                                       |
| Ptosis with diplopia                                          | Look at eye position and pupils                                        | <b>CN III or NMJ; mild ptosis+miosis suggests sympathetic pathway</b> |
| Ptosis/diplopia fluctuates and worsens later in day           | Sustained upgaze; repeated saccades; look for fatigability             | <b>Neuromuscular junction — myasthenia</b>                            |
| Sudden headache with ptosis and diplopia                      | Look for complete III palsy and pupil enlargement                      | <b>Compressive CN III lesion; PCom aneurysm is an important cause</b> |
| Diabetes/HTN with painless diplopia and ptosis                | III palsy with preserved pupillary response                            | <b>Microvascular CN III palsy</b>                                     |
| Both eyes cannot look toward one side                         | Test conjugate horizontal gaze                                         | <b>Ipsilateral PPRF or abducens nucleus — pons</b>                    |
| One eye fails to adduct; opposite eye has abducting nystagmus | Test horizontal gaze and convergence                                   | <b>Ipsilateral MLF — internuclear ophthalmoplegia</b>                 |
| Diplopia + facial numbness                                    | Test III/IV/VI and V1/V2 sensation/corneal reflex                      | <b>Cavernous sinus / parasellar region</b>                            |

| Positive history findings / what to ask                        | Positive examination findings / what to elicit                    | Structure / localisation                                |
|----------------------------------------------------------------|-------------------------------------------------------------------|---------------------------------------------------------|
| Diplopia + visual loss                                         | Visual acuity, colour vision, RAPD plus ocular movements          | <b>Orbital apex / optic nerve + ocular motor nerves</b> |
| Diplopia + contralateral weakness                              | Full cranial nerve and UMN examination                            | <b>Brainstem — midbrain or pons</b>                     |
| Diplopia + vertigo/ataxia                                      | Nystagmus, skew, limb/gait coordination                           | <b>Brainstem/cerebellum / vestibular pathways</b>       |
| Difficulty looking upward rather than isolated muscle weakness | Upgaze, convergence-retraction nystagmus, light-near dissociation | <b>Dorsal rostral midbrain — Parinaud region</b>        |

**How to think:** First prove this is language dysfunction, not dysarthria, hearing loss, delirium or low consciousness. Test fluency, comprehension, repetition, naming, reading and writing.

| Positive history findings / what to ask                                       | Positive examination findings / what to elicit                                    | Structure / localisation                                                    |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Knows what they want to say but cannot get words out; short effortful answers | Nonfluent speech; relatively preserved comprehension; impaired naming/ repetition | <b>Dominant inferior frontal cortex — Broca/perisylvian frontal network</b> |
| Speaks fluently but family says speech makes no sense                         | Fluent paraphasic speech; poor comprehension and repetition                       | <b>Dominant posterior superior temporal cortex — Wernicke network</b>       |
| Does the patient understand conversation?                                     | One-step then multistep verbal commands                                           | <b>Posterior temporal language comprehension network</b>                    |
| Difficulty finding names of familiar objects                                  | Name pen/watch/body parts; describe object use                                    | <b>Dominant temporal–temporoparietal naming network</b>                     |
| Fluent speech and comprehension good, but cannot repeat                       | Repeat phrases of increasing complexity                                           | <b>Arcuate fasciculus/supramarginal region — conduction aphasia</b>         |

| Positive history findings / what to ask                     | Positive examination findings / what to elicit                 | Structure / localisation                                                                   |
|-------------------------------------------------------------|----------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Nonfluent speech but repetition surprisingly preserved      | Fluency ↓, comprehension relatively good, repetition preserved | <b>Dominant anterior watershed / medial frontal language network — transcortical motor</b> |
| Fluent speech, poor comprehension, but repetition preserved | Confirm preserved repetition despite poor comprehension        | <b>Posterior watershed / temporoparietal association cortex — transcortical sensory</b>    |
| Severe impairment of speech and comprehension               | Nonfluent + poor comprehension + poor repetition               | <b>Large dominant perisylvian/MCA territory — global aphasia</b>                           |
| Difficulty reading                                          | Read aloud; obey a written command; test reading comprehension | <b>Dominant occipitotemporal/angular language pathway</b>                                  |
| Cannot read but can still write                             | Ask spontaneous writing then ask patient to read it            | <b>Left occipital cortex + splenium — alexia without agraphia</b>                          |
| Difficulty writing                                          | Spontaneous sentence, dictated sentence and copying            | <b>Dominant parietal/angular or broader dominant language network</b>                      |
| Calculation/right-left/finger identification difficulty     | Acalculia, agraphia, finger agnosia, right-left disorientation | <b>Dominant angular gyrus — Gerstmann pattern</b>                                          |
| Understands command but cannot demonstrate learned action   | Pantomime brushing teeth, using a key or salute                | <b>Dominant parietal–premotor praxis network</b>                                           |

| Positive history findings / what to ask         | Positive examination findings / what to elicit | Structure / localisation                                     |
|-------------------------------------------------|------------------------------------------------|--------------------------------------------------------------|
| Aphasia with face/arm weakness greater than leg | Right lower facial and arm UMN signs           | <b>Dominant lateral hemisphere — usually left MCA cortex</b> |

03

## Weakness — proximal vs distal

Use function, distribution, tone, reflexes and sensation to move from muscle to nerve to cord to brain

**How to think:** Do not stop at “power 4/5”. Ask what daily task fails and whether weakness is proximal or distal, symmetric or asymmetric, fatigable, painful, spastic or associated with sensory loss.

| Positive history findings / what to ask                   | Positive examination findings / what to elicit              | Structure / localisation                         |
|-----------------------------------------------------------|-------------------------------------------------------------|--------------------------------------------------|
| Difficulty combing hair/reaching overhead                 | Shoulder abduction and external rotation; scapular movement | <b>Proximal upper limb — muscle or C5–C6</b>     |
| Difficulty rising from chair without hands                | Hip flexion/extension; sit-to-stand                         | <b>Proximal pelvic-girdle muscles / myopathy</b> |
| Difficulty climbing stairs or getting up from squat/floor | Hip and knee proximal power; Gowers-type manoeuvre          | <b>Proximal lower limb / myopathy</b>            |

| Positive history findings / what to ask                           | Positive examination findings / what to elicit               | Structure / localisation                                         |
|-------------------------------------------------------------------|--------------------------------------------------------------|------------------------------------------------------------------|
| Difficulty buttoning, turning key, opening bottle                 | Finger abduction, opposition, grip, finger flexion/extension | <b>Distal upper limb — C8–T1/root/plexus/median-ulnar-radial</b> |
| Foot slaps or trips over toes                                     | Heel walking; dorsiflexion and toe extension                 | <b>L4–L5/deep or common peroneal pathway</b>                     |
| Cannot stand on toes                                              | Single-leg heel raise; plantarflexion; Achilles reflex       | <b>S1–S2 / tibial nerve</b>                                      |
| Symmetric proximal > distal weakness, no sensory loss             | Proximal power, reflexes, muscle bulk                        | <b>Muscle / myopathy</b>                                         |
| Proximal weakness + ptosis/ophthalmoplegia + fatigability         | Sustained upgaze; repetitive proximal movements              | <b>Neuromuscular junction — myasthenia</b>                       |
| Proximal weakness improves briefly after activity; dry mouth      | Reduced reflexes with post-exercise facilitation             | <b>Presynaptic NMJ — Lambert-Eaton</b>                           |
| Distal > proximal weakness + sensory symptoms                     | Distal sensory loss and reduced reflexes                     | <b>Peripheral neuropathy</b>                                     |
| Weakness with neck/back radicular pain and dermatomal paresthesia | Myotomal power, reflex and dermatomal sensory testing        | <b>Nerve root</b>                                                |

| Positive history findings / what to ask                        | Positive examination findings / what to elicit          | Structure / localisation                                      |
|----------------------------------------------------------------|---------------------------------------------------------|---------------------------------------------------------------|
| Several muscles from different nerves share one myotome        | Map muscles by root rather than named nerve             | <b>Radiculopathy</b>                                          |
| Weakness fits one named nerve plus its cutaneous territory     | Named-nerve motor and sensory testing                   | <b>Peripheral mononeuropathy</b>                              |
| Weakness crosses several named nerves with patchy sensory loss | Map root/nerve combinations                             | <b>Plexus</b>                                                 |
| Distal wasting/fasciculation without sensory loss              | Fasciculations, atrophy, reflexes                       | <b>Anterior horn cell</b>                                     |
| Wasting/fasciculation plus brisk reflexes/ Babinski            | Look for UMN+LMN signs in multiple regions              | <b>Motor neuron system</b>                                    |
| Spastic weakness with brisk reflexes/ Babinski                 | Tone, reflexes, plantar responses                       | <b>Corticospinal tract — brain or spinal cord</b>             |
| Face + arm + leg weakness on one side                          | Look for cortical signs and crossed cranial-nerve signs | <b>Contralateral hemisphere/internal capsule or brainstem</b> |
| Face/arm weakness greater than leg                             | Motor homunculus distribution; language/ neglect        | <b>Lateral motor cortex — MCA territory</b>                   |

| Positive history findings / what to ask                         | Positive examination findings / what to elicit     | Structure / localisation                           |
|-----------------------------------------------------------------|----------------------------------------------------|----------------------------------------------------|
| Leg weakness greater than arm                                   | Leg power, frontal signs, bladder symptoms         | <b>Medial frontal motor cortex — ACA territory</b> |
| Dense proportional face-arm-leg weakness without cortical signs | No aphasia/neglect/field defect; pure UMN pattern  | <b>Internal capsule</b>                            |
| LMN weakness/wasting in arms + UMN signs in legs                | Segmental arm reflex loss + brisk legs/ Babinski   | <b>Cervical spinal cord</b>                        |
| Bilateral UMN leg weakness, arms normal                         | Sensory level; brisk legs; Babinski                | <b>Thoracic spinal cord</b>                        |
| Asymmetric painful flaccid legs + absent reflexes               | Saddle sensation, root pattern, anal tone          | <b>Cauda equina</b>                                |
| Dorsiflexion + eversion weak; inversion preserved               | Test inversion and hip abduction                   | <b>Common peroneal nerve</b>                       |
| Dorsiflexion + inversion + hip abduction weak                   | L5 sensory pattern; ankle jerk often preserved     | <b>L5 root</b>                                     |
| Dorsiflexion and plantarflexion both weak                       | Hamstrings, ankle jerk and broad foot sensory loss | <b>Sciatic nerve</b>                               |

## Gait abnormality

Ask whether the gait problem is weakness, spasticity, ataxia, sensory loss, vestibular dysfunction, parkinsonism or frontal gait control

**How to think:** Describe the gait before naming it. Then test tone, reflexes, plantar responses, proprioception, Romberg, limb coordination, eye movements and distal power.

| Positive history findings / what to ask    | Positive examination findings / what to elicit                    | Structure / localisation                                    |
|--------------------------------------------|-------------------------------------------------------------------|-------------------------------------------------------------|
| One leg stiff and swings outward           | Circumduction; flexed ipsilateral arm; brisk reflexes/Babinski    | <b>Contralateral corticospinal tract — hemiparetic gait</b> |
| Both legs stiff; feet may cross            | Spastic/scissoring gait; adductor tone ↑; brisk knees; Babinski   | <b>Bilateral corticospinal tracts / spinal cord</b>         |
| Feet slap; trips over toes                 | High-stepping gait; dorsiflexion weakness                         | <b>Distal LMN pathway / L5 / peroneal nerve</b>             |
| Worse in darkness; watches feet            | Stamping gait; positive Romberg; loss of vibration/joint position | <b>Posterior columns / large sensory fibres</b>             |
| Broad-based, staggering, difficult turning | Wide base, irregular steps, impaired tandem walk                  | <b>Cerebellum</b>                                           |

| Positive history findings / what to ask                         | Positive examination findings / what to elicit                 | Structure / localisation                                    |
|-----------------------------------------------------------------|----------------------------------------------------------------|-------------------------------------------------------------|
| Falls consistently toward one side                              | Limb dysmetria; nystagmus; vestibular testing                  | <b>Ipsilateral cerebellar/vestibular system</b>             |
| Main problem is truncal instability, little limb incoordination | Truncal titubation; severe tandem impairment                   | <b>Cerebellar vermis</b>                                    |
| Vertigo and veering to one side                                 | Nystagmus; head impulse; gait veering/falling                  | <b>Vestibular apparatus/CN VIII/brainstem</b>               |
| Small steps, freezing, difficulty starting/turning              | Stooped posture; reduced arm swing; shuffling; en-bloc turning | <b>Basal ganglia — parkinsonism</b>                         |
| Feet seem 'stuck to floor'; cognition/bladder symptoms          | Magnetic gait; short steps; broad base; initiation difficulty  | <b>Frontal-subcortical gait network</b>                     |
| Legs buckle; difficulty rising from chair                       | Proximal power; Gowers-type manoeuvre; waddling gait           | <b>Pelvic-girdle muscle</b>                                 |
| Pelvis drops on opposite side while standing on one leg         | Trendelenburg sign; trunk lean toward weak side                | <b>Gluteus medius/minimus / superior gluteal nerve / L5</b> |
| Radicular leg pain while walking                                | Root-specific weakness/reflex/sensory loss                     | <b>Radiculopathy</b>                                        |

| Positive history findings / what to ask    | Positive examination findings / what to elicit | Structure / localisation                       |
|--------------------------------------------|------------------------------------------------|------------------------------------------------|
| Progressive stiff gait + urinary urgency   | Spastic paraparesis + sensory level + Babinski | <b>Spinal cord myelopathy</b>                  |
| Unsteady because knees/feet cannot be felt | Positive Romberg; proprioceptive loss          | <b>Dorsal columns / large-fibre neuropathy</b> |
| Unsteady even with eyes open               | Dysmetria/dysdiadochokinesia/nystagmus         | <b>Cerebellum</b>                              |

05

## Numbness / sensory symptoms

Map the sensory pattern before interpreting modality

**How to think:** The distribution often localises first: hemisensory, crossed face-body, sensory level, dermatome, named nerve, stocking-glove or saddle.

| Positive history findings / what to ask | Positive examination findings / what to elicit | Structure / localisation                       |
|-----------------------------------------|------------------------------------------------|------------------------------------------------|
| Face, arm and leg numb on the same side | Test all modalities over face and body         | <b>Contralateral thalamus / sensory cortex</b> |

| Positive history findings / what to ask     | Positive examination findings / what to elicit               | Structure / localisation                        |
|---------------------------------------------|--------------------------------------------------------------|-------------------------------------------------|
| Face one side + body opposite side          | Pain-temperature over face and limbs                         | <b>Brainstem</b>                                |
| Numbness below a horizontal line on trunk   | Map pinprick upward to define level                          | <b>Spinal cord</b>                              |
| Band-like chest/abdominal sensation         | Dermatomal level; UMN leg signs                              | <b>Thoracic cord or root</b>                    |
| Shooting pain from back into limb           | Dermatomal sensory loss + root-specific weakness/reflex loss | <b>Nerve root</b>                               |
| Numbness in one named nerve territory       | Map cutaneous distribution                                   | <b>Peripheral nerve</b>                         |
| Glove-and-stockings numbness                | Distal pinprick/vibration loss + absent ankle jerks          | <b>Length-dependent peripheral neuropathy</b>   |
| Worse balance in darkness                   | Vibration, joint position, Romberg                           | <b>Posterior columns / large sensory fibres</b> |
| Burns/injuries without noticing temperature | Pain-temperature lost but vibration preserved                | <b>Central cord / syrinx</b>                    |
| Saddle numbness                             | Perianal sensation, anal tone, sacral reflexes               | <b>Conus / cauda equina</b>                     |

**How to think:** Look for hearing symptoms, positional triggers, severe truncal ataxia and associated cranial-nerve or long-tract symptoms.

| Positive history findings / what to ask                   | Positive examination findings / what to elicit | Structure / localisation                                     |
|-----------------------------------------------------------|------------------------------------------------|--------------------------------------------------------------|
| True spinning sensation                                   | Observe spontaneous nystagmus                  | <b>Vestibular system</b>                                     |
| Sudden vertigo lasting hours-days with nausea/vomiting    | Head impulse, nystagmus, skew                  | <b>Peripheral vestibular vs central brainstem/cerebellum</b> |
| Vertigo + hearing loss/tinnitus                           | Bedside hearing; otologic exam                 | <b>Labyrinth/CN VIII/AICA</b>                                |
| Seconds-long vertigo triggered by turning in bed          | Dix-Hallpike                                   | <b>Posterior semicircular canal — BPPV</b>                   |
| Unable to stand or walk despite little subjective vertigo | Truncal/gait ataxia                            | <b>Cerebellum</b>                                            |
| Vertigo + diplopia/dysarthria/dysphagia                   | Cranial nerves, cerebellar and long-tract exam | <b>Brainstem / posterior circulation</b>                     |

| Positive history findings / what to ask                    | Positive examination findings / what to elicit | Structure / localisation                         |
|------------------------------------------------------------|------------------------------------------------|--------------------------------------------------|
| Vertigo + facial sensory loss + opposite body sensory loss | Crossed sensory examination                    | <b>Lateral medulla/pons</b>                      |
| Veers consistently to one side                             | Tandem gait; limb coordination                 | <b>Ipsilateral vestibular/cerebellar pathway</b> |

07

## Dysarthria, dysphagia & dysphonia

Differentiate language, articulation and voice

**How to think:** Aphasia = language. Dysarthria = articulation. Dysphonia = voice/larynx. Dysphagia may localise to corticobulbar, bulbar, NMJ or muscle.

| Positive history findings / what to ask       | Positive examination findings / what to elicit            | Structure / localisation                 |
|-----------------------------------------------|-----------------------------------------------------------|------------------------------------------|
| Speech slurred but words/language appropriate | Articulation testing; repetition of lingual/labial sounds | <b>Motor speech pathway — dysarthria</b> |
| Nasal speech + nasal regurgitation            | Palatal elevation                                         | <b>CN X / nucleus ambiguus</b>           |

| Positive history findings / what to ask            | Positive examination findings / what to elicit              | Structure / localisation                      |
|----------------------------------------------------|-------------------------------------------------------------|-----------------------------------------------|
| Hoarse voice                                       | Listen to phonation/cough; vocal cord examination if needed | <b>CN X / recurrent laryngeal</b>             |
| Chokes mainly on liquids                           | Palate, gag, cough                                          | <b>Oropharyngeal/bulbar pathway</b>           |
| Food remains in mouth / hard to manipulate bolus   | Tongue movements                                            | <b>CN XII</b>                                 |
| Weak cough                                         | Cough strength                                              | <b>CN X / bulbar muscles</b>                  |
| Tongue wasting/fasciculation                       | Inspect tongue at rest and protrusion                       | <b>LMN XII / bulbar motor neuron</b>          |
| Brisk jaw jerk + slow stiff tongue without wasting | Jaw jerk, gag, limb UMN signs                               | <b>Bilateral corticobulbar — pseudobulbar</b> |
| Dysarthria + ipsilateral limb ataxia               | Finger-nose, heel-shin                                      | <b>Cerebellum/brainstem</b>                   |
| Dysarthria + clumsy hand, no aphasia               | Fine hand movements and pyramidal signs                     | <b>Pons/internal capsule lacune</b>           |

# Visual loss / field disturbance

Use monocular vs binocular and field geometry to map the optic pathway

**How to think:** One eye = retina/optic nerve. Bitemporal = chiasm. Homonymous = retrochiasmal.

| Positive history findings / what to ask          | Positive examination findings / what to elicit | Structure / localisation                      |
|--------------------------------------------------|------------------------------------------------|-----------------------------------------------|
| Sudden painless monocular blindness              | Visual acuity, RAPD, fundus                    | <b>Retina / optic nerve</b>                   |
| Pain on eye movement + colour desaturation       | RAPD, red desaturation, central field          | <b>Optic nerve</b>                            |
| Progressive peripheral visual loss in both eyes  | Confrontation fields                           | <b>Optic chiasm</b>                           |
| Same side of visual world missing from both eyes | Homonymous field testing                       | <b>Retrochiasmal pathway</b>                  |
| Upper quadrant missing                           | Formal/confrontation fields                    | <b>Contralateral temporal Meyer loop</b>      |
| Lower quadrant missing                           | Formal/confrontation fields                    | <b>Contralateral parietal optic radiation</b> |
| Hemianopia with otherwise normal neurologic exam | Congruity + macular sparing                    | <b>Occipital cortex</b>                       |

| Positive history findings / what to ask       | Positive examination findings / what to elicit | Structure / localisation          |
|-----------------------------------------------|------------------------------------------------|-----------------------------------|
| Cannot recognise faces despite seeing clearly | Face recognition                               | <b>Fusiform cortex</b>            |
| Cannot see but pupils remain reactive         | Pupillary reflexes, fundus                     | <b>Bilateral occipital cortex</b> |
| Visual loss + ophthalmoplegia                 | RAPD + ocular movements                        | <b>Orbital apex</b>               |

09

## Bladder, bowel & sexual dysfunction

These symptoms can sharply separate cord, conus and cauda

**How to think:** Always ask in bilateral leg weakness: difficulty passing urine? altered perianal/genital sensation? bowel or sexual dysfunction?

| Positive history findings / what to ask | Positive examination findings / what to elicit | Structure / localisation                 |
|-----------------------------------------|------------------------------------------------|------------------------------------------|
| Urgency/frequency with stiff legs       | UMN legs + sensory level                       | <b>Spinal cord above sacral segments</b> |

| Positive history findings / what to ask                            | Positive examination findings / what to elicit | Structure / localisation         |
|--------------------------------------------------------------------|------------------------------------------------|----------------------------------|
| Sudden urinary retention + saddle numbness                         | Perianal sensation, anal tone, sacral reflexes | <b>Conus/cauda</b>               |
| Very early bladder symptoms with relatively symmetric leg deficits | Sacral exam; mixed UMN/LMN signs               | <b>Conus medullaris</b>          |
| Severe radicular pain then later bladder retention                 | LMN legs; root sensory loss                    | <b>Cauda equina</b>              |
| Loss of awareness of bladder filling                               | Sacral sensation/autonomic assessment          | <b>Sacral cord/root pathways</b> |
| Erectile/sexual dysfunction + saddle sensory loss                  | S2–S4 sensory/autonomic assessment             | <b>Conus / sacral roots</b>      |

# Tremor & involuntary movements

First define the movement phenomenology; then localise the motor network

**How to think:** Rest tremor, intention tremor, ballistic movement, chorea, myoclonus and bradykinesia point to different networks.

| Positive history findings / what to ask    | Positive examination findings / what to elicit     | Structure / localisation                                        |
|--------------------------------------------|----------------------------------------------------|-----------------------------------------------------------------|
| Tremor when hand is resting                | Observe hands at rest while distracted             | <b>Basal ganglia / parkinsonian pathway</b>                     |
| Tremor appears as finger approaches target | Finger-nose testing                                | <b>Cerebellum</b>                                               |
| Tremor during posture/action               | Arms outstretched; writing/spiral                  | <b>Action tremor networks</b>                                   |
| Violent flinging of one side               | Observe proximal ballistic movements               | <b>Contralateral subthalamic nucleus</b>                        |
| Irregular flowing purposeless movements    | Observe face/limbs/tongue                          | <b>Striatum / chorea</b>                                        |
| Brief shock-like jerks                     | Characterise distribution and stimulus sensitivity | <b>Myoclonus — cortex/subcortex/brainstem depending context</b> |

| Positive history findings / what to ask   | Positive examination findings / what to elicit | Structure / localisation                       |
|-------------------------------------------|------------------------------------------------|------------------------------------------------|
| Slowness rather than true weakness        | Finger taps, pronation-supination, foot taps   | <b>Basal ganglia / bradykinesia</b>            |
| Abnormal movement disappears during sleep | Observation and history                        | <b>Supports hyperkinetic movement disorder</b> |

11

## Headache

Headache itself usually does not localise — associated neurological findings do

**How to think:** Define onset, speed to peak, position/Valsalva relation, fever, visual symptoms, focal deficits and cranial-nerve symptoms.

| Positive history findings / what to ask                                        | Positive examination findings / what to elicit | Structure / localisation                   |
|--------------------------------------------------------------------------------|------------------------------------------------|--------------------------------------------|
| Sudden 'worst-ever' headache reaching maximum intensity within seconds/minutes | Neck stiffness, consciousness, focal deficits  | <b>Subarachnoid space / aneurysmal SAH</b> |

| Positive history findings / what to ask                                      | Positive examination findings / what to elicit  | Structure / localisation                        |
|------------------------------------------------------------------------------|-------------------------------------------------|-------------------------------------------------|
| Headache + focal weakness, aphasia or field deficit                          | Full cortical examination                       | <b>Cerebral hemisphere / vascular lesion</b>    |
| Headache + vomiting + progressive visual blurring, worse in morning/coughing | Fundoscopy, CN VI, consciousness                | <b>Raised intracranial pressure</b>             |
| Headache worse on coughing/sneezing/straining                                | Papilledema, CN VI palsy, cerebellar signs      | <b>Raised ICP / posterior fossa lesion</b>      |
| Occipital headache + vomiting + gait unsteadiness                            | Gait, nystagmus, limb coordination              | <b>Posterior fossa / cerebellum</b>             |
| Headache + diplopia + multiple ocular motor palsies                          | III, IV, VI and V1/V2 examination               | <b>Cavernous sinus / orbital apex</b>           |
| Retro-orbital pain + visual loss                                             | Acuity, colour vision, RAPD                     | <b>Optic nerve / orbit</b>                      |
| Headache + painful pupil-involving III palsy                                 | Pupil and ocular movements                      | <b>PCom region / compressive CN III</b>         |
| Headache + neck pain followed by Horner or posterior circulation symptoms    | Horner signs; cranial nerves; cerebellar exam   | <b>Carotid/vertebral artery dissection</b>      |
| New unilateral headache + transient monocular visual loss in older adult     | Temporal artery tenderness/pulse; visual acuity | <b>Temporal artery / ischemic optic pathway</b> |

| Positive history findings / what to ask                              | Positive examination findings / what to elicit | Structure / localisation                                     |
|----------------------------------------------------------------------|------------------------------------------------|--------------------------------------------------------------|
| Headache + fever + neck stiffness                                    | Meningism, consciousness, cranial nerves       | <b>Meninges</b>                                              |
| Headache + fever + focal deficit/seizure                             | Fundus and focal cortical examination          | <b>Brain abscess/encephalitis/focal intracranial process</b> |
| Progressive headache + personality/behavioural change                | Frontal release signs, executive function      | <b>Frontal lobe</b>                                          |
| Headache + endocrine symptoms + visual-field loss                    | Bitemporal fields; ocular movements            | <b>Sellar/suprasellar region</b>                             |
| Headache + papilledema + VI palsy without other focal signs          | Fundoscopy and abduction                       | <b>Raised ICP</b>                                            |
| Headache precipitated by posture/cough/Valsalva + occipital symptoms | Lower cranial nerves and long-tract signs      | <b>Foramen magnum / craniocervical junction</b>              |

12

## Syncope / transient loss of consciousness

First decide whether this was true syncope, seizure or another transient neurologic event

**How to think:** True syncope reflects transient global cerebral hypoperfusion and usually does not localise to one lobe.

| Positive history findings / what to ask                       | Positive examination findings / what to elicit | Structure / localisation                                       |
|---------------------------------------------------------------|------------------------------------------------|----------------------------------------------------------------|
| LOC after prolonged standing, heat, pain or emotional trigger | Lying/standing BP, pulse                       | <b>Systemic autonomic/cardiovascular rather than focal CNS</b> |
| Prodrome of nausea, sweating, warmth, dimming vision          | Orthostatic vitals; cardiovascular exam        | <b>Vasovagal/autonomic pathway</b>                             |
| LOC immediately after standing                                | Orthostatic BP and pulse                       | <b>Autonomic nervous system / volume depletion</b>             |
| Sudden LOC without warning during exertion                    | Cardiac examination; rhythm assessment         | <b>Cardiac rather than neurological localisation</b>           |
| Palpitations before LOC                                       | Pulse/rhythm assessment                        | <b>Arrhythmic/cardiac source</b>                               |
| Brief LOC with rapid recovery and no confusion                | Neurological exam usually normal               | <b>Syncope rather than cortical seizure</b>                    |

| Positive history findings / what to ask                                 | Positive examination findings / what to elicit | Structure / localisation                                      |
|-------------------------------------------------------------------------|------------------------------------------------|---------------------------------------------------------------|
| Brief jerking only after becoming unconscious                           | Look for absence of prolonged postictal focal  | <b>Convulsive syncope can occur</b>                           |
| Tongue bite, prolonged confusion or stereotyped aura                    | Search for focal neurological signs            | <b>Cortical seizure network</b>                               |
| LOC + diplopia/dysarthria/ataxia/bilateral weakness                     | Cranial nerves/cerebellar/long-tract exam      | <b>Brainstem/posterior circulation</b>                        |
| LOC with persistent unilateral weakness afterward                       | Define fixed vs transient deficit              | <b>Contralateral hemisphere; consider Todd paresis/stroke</b> |
| Recurrent syncope + impaired sweating/erectile dysfunction/constipation | Orthostatic BP; autonomic exam                 | <b>Autonomic nervous system</b>                               |

13

# Seizure

The earliest ictal symptom is often the most localising

**How to think:** Ask 'what happened first?' before the seizure spread or generalised.

| Positive history findings / what to ask                  | Positive examination findings / what to elicit                 | Structure / localisation                                  |
|----------------------------------------------------------|----------------------------------------------------------------|-----------------------------------------------------------|
| Jerking began in one hand and marched up arm toward face | Examine opposite motor cortex functions; look for Todd paresis | <b>Contralateral primary motor cortex</b>                 |
| Jerking began in face then spread to arm/leg             | Postictal opposite weakness                                    | <b>Contralateral motor cortex</b>                         |
| Forced head and eyes turned to one side at onset         | Determine direction of version                                 | <b>Usually frontal eye field opposite the forced gaze</b> |
| Tingling started in one hand and spread up arm           | Cortical sensory testing                                       | <b>Contralateral postcentral gyrus</b>                    |
| Flashing lights/coloured shapes                          | Visual fields                                                  | <b>Occipital cortex</b>                                   |
| Complex visual scenes/familiar people before seizure     | Visual recognition and temporal/occipitotemporal function      | <b>Visual association cortex</b>                          |

| Positive history findings / what to ask               | Positive examination findings / what to elicit | Structure / localisation                             |
|-------------------------------------------------------|------------------------------------------------|------------------------------------------------------|
| Rising epigastric sensation before impaired awareness | Memory/temporal examination                    | <b>Mesial temporal lobe</b>                          |
| Déjà vu, jamais vu or sudden intense fear             | Memory/behaviour examination                   | <b>Mesial temporal lobe / amygdala</b>               |
| Unpleasant smell or taste before seizure              | Olfaction and temporal function                | <b>Uncus / mesial temporal cortex</b>                |
| Brief auditory hallucination or distorted sounds      | Hearing/language exam                          | <b>Superior temporal cortex</b>                      |
| Speech arrest at onset                                | Language testing                               | <b>Dominant frontal/perisylvian cortex</b>           |
| Cannot understand language during attack              | Comprehension testing                          | <b>Dominant posterior temporal cortex</b>            |
| Lip smacking, chewing or picking automatisms          | Memory examination                             | <b>Temporal-limbic network</b>                       |
| Sudden tonic posturing of one limb                    | Look for focal UMN deficit afterward           | <b>Contralateral frontal motor network</b>           |
| Seizure followed by transient unilateral weakness     | Document Todd paresis pattern and duration     | <b>Opposite motor cortex involved during seizure</b> |
| Seizure followed by transient aphasia                 | Detailed language examination                  | <b>Dominant hemisphere</b>                           |

| Positive history findings / what to ask                     | Positive examination findings / what to elicit  | Structure / localisation                                                           |
|-------------------------------------------------------------|-------------------------------------------------|------------------------------------------------------------------------------------|
| Seizure followed by transient visual deficit                | Visual-field testing                            | <b>Occipital/retrochiasmal cortex</b>                                              |
| Behavioural arrest with staring                             | Automatisms, awareness and post-event confusion | <b>Temporal network if focal; generalized network if typical absence phenotype</b> |
| Bilateral tonic-clonic activity without obvious focal onset | Ask carefully for preceding focal aura          | <b>May be focal-to-bilateral or generalized network</b>                            |

## Memory loss

Separate attention, registration, storage, retrieval and remote memory

**How to think:** Before calling it memory loss, exclude impaired attention, aphasia, delirium, depression and executive dysfunction.

| Positive history findings / what to ask                 | Positive examination findings / what to elicit | Structure / localisation                   |
|---------------------------------------------------------|------------------------------------------------|--------------------------------------------|
| Repeatedly asks same question and forgets recent events | Delayed recall and new learning                | <b>Hippocampus / medial temporal lobes</b> |

| Positive history findings / what to ask                      | Positive examination findings / what to elicit   | Structure / localisation                                           |
|--------------------------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------|
| Remembers childhood but cannot retain today's events         | Immediate vs delayed recall                      | <b>Medial temporal memory consolidation system</b>                 |
| Cannot form new memories after an event                      | Learning of new words/objects                    | <b>Bilateral hippocampi</b>                                        |
| Lost memories of events before illness                       | Establish temporal gradient of retrograde memory | <b>Distributed cortical memory stores / medial temporal access</b> |
| Forgetful with poor attention and fluctuating consciousness  | Digit span; months backward                      | <b>Diffuse cortical/subcortical dysfunction</b>                    |
| 'Forgetful' because patient cannot organise/plan/retrieve    | Executive tests; verbal fluency                  | <b>Frontal-subcortical circuits</b>                                |
| Memory improves substantially with cues/ recognition choices | Free recall vs recognition                       | <b>Frontal retrieval dysfunction more than hippocampal storage</b> |
| Both recall and recognition poor despite adequate attention  | Delayed recall and recognition                   | <b>Hippocampal storage/consolidation problem</b>                   |
| Memory loss + personality change/ disinhibition              | Frontal and temporal examination                 | <b>Frontotemporal networks</b>                                     |
| Memory loss + confabulation                                  | Orientation, recall, executive control           | <b>Diencephalic/frontal memory circuits</b>                        |

| Positive history findings / what to ask                          | Positive examination findings / what to elicit         | Structure / localisation                                                         |
|------------------------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------|
| Memory loss + gait ataxia + ophthalmoplegia                      | Eye movements, gait, confusion                         | <b>Mammillary bodies/medial thalamus — Wernicke network</b>                      |
| Sudden severe anterograde amnesia with preserved identity        | Repetitive questioning; attention relatively preserved | <b>Bilateral hippocampal memory network / transient global amnesia phenotype</b> |
| Memory loss + vertical gaze palsy/ hypersomnolence               | Consciousness and vertical eye movements               | <b>Paramedian thalami</b>                                                        |
| Verbal memory poor; visual memory relatively preserved           | Compare verbal learning with visual memory             | <b>Dominant medial temporal lobe</b>                                             |
| Visual/spatial memory poor; verbal learning relatively preserved | Visual reproduction/route memory                       | <b>Nondominant medial temporal network</b>                                       |

Educational bedside localisation aid. Use clinical context and appropriate investigations to confirm diagnosis.
